Did you know that...?

Humpback whales are among the loudest animals on Earth. Their songs can travel through the ocean for hundreds or even thousands of kilometers.
Whale songs are not random sounds. They consist of repeating patterns and sequences of tones that can last for several minutes before repeating again.
The songs of humpback whales change over time. Scientists have discovered that new melodies can spread between whale
populations much like popular songs spread among people.
Sound travels much better underwater than it does through air. This allows whales to communicate across vast distances throughout the ocean.
