Did you know that...?

IQcoloring.com

A sea star can regrow a lost or damaged arm when enough of its central body remains intact.
The new arm first appears as a small developing growth and gradually becomes longer until it begins to resemble the other arms.
Regeneration can take a long time, and the growing arm remains noticeably shorter than the others during the process.
This remarkable ability helps sea stars restore parts of their body that may have been damaged by strong waves or other events.
