Did you know that...?

Seahorses are among the few fish that swim in an upright position instead of moving horizontally through the water. They are propelled mainly by their small dorsal fin, which can flutter so quickly that its movement is often difficult for the human eye to see. Small pectoral fins near the head help them change direction and remain stable in the water. Seahorses are not very fast swimmers, so in stronger currents they often use their prehensile tails to hold onto marine plants.
