Did you know that...?

Adélie penguins live in Antarctica and are easily recognized by the distinctive white rings around their eyes, one of their most recognizable features.
Unlike emperor penguins, Adélie penguins build nests from small pebbles that help protect their eggs from wet ground and water produced by melting snow.
When building their nests, penguins carry individual pebbles in their beaks and sometimes even steal stones from neighboring nests, which can lead to small disputes between neighbors.
Female Adélie penguins usually lay two eggs, and both parents take turns incubating them and later caring for their chicks while the other parent travels to sea to find food.
Adélie penguins nest in large colonies that can contain thousands of breeding pairs, and they feed mainly on krill, fish, and other small marine animals.
